

On a geometric equation with critical nonlinearity on the boundary

VERONICA FELLI AND MOHAMEDEN OULD AHMEDOU

Abstract

A theorem of Escobar asserts that, on a positive three dimensional smooth compact Riemannian manifold with boundary which is not conformally equivalent to the standard three dimensional ball, a necessary and sufficient condition for a C^2 function H to be the mean curvature of some conformal scalar flat metric is that H is positive somewhere. We show that, when the boundary is umbilic and the function H is positive everywhere, all such metrics stay in a compact set with respect to the C^2 norm and the total degree of all solutions is equal to -1 .

MSC classification: 35J60, 53C21, 58G30.

1 Introduction

In [14], José F. Escobar raised the following question: given a compact Riemannian manifold with boundary, when is it conformally equivalent to one that has zero scalar curvature and whose boundary has a constant mean curvature? This problem can be seen as a “generalization” to higher dimensions of the well known Riemannian Mapping Theorem. The later states that an open, simply connected proper subset of the plane is conformally diffeomorphic to the disk. In higher dimensions few regions are conformally diffeomorphic to the ball. However one can still ask whether a domain is conformal to a manifold that resembles the ball in two ways: namely, it has zero scalar curvature and its boundary has constant mean curvature. The above problem is equivalent to finding a smooth positive solution u to the following nonlinear boundary value problem on a Riemannian manifold with boundary (M^n, g) , $n \geq 3$:

$$\begin{cases} -\Delta_g u + \frac{(n-2)}{4(n-1)} R_g u = 0, & u > 0, \quad \text{in } \overset{\circ}{M}, \\ \frac{\partial u}{\partial \nu} + \frac{n-2}{2} h_g u = c u^{\frac{n}{n-2}}, & \text{on } \partial M, \end{cases} \quad (P)$$

where R_g is the scalar curvature of M , h_g is the mean curvature of ∂M , ν is the outer normal vector with respect to g , and c is a constant whose sign is uniquely determined by the conformal structure.

For almost all manifolds, Escobar [14, 16] established that (P) has a solution. More recently in [29] this problem has been studied using the tools of the critical points at infinity of A. Bahri [2], see also Bahri-Coron [4] and Bahri-Brezis [3]. Going beyond the existence results of the above paper, we proved recently in [18] that, when (M, g) is locally conformally flat with umbilic boundary but not conformal to the standard ball, all solutions of (P) stay in a compact set with respect to the C^2 norm and the total degree of all solutions is equal to -1 .

The heart of the proof of the above result is some fine analysis of possible blow-up behaviour of solutions to (P) . More specifically we obtained energy independent estimates of solutions to

$$\begin{cases} L_g u = 0, & u > 0, & \text{in } \overset{\circ}{M}, \\ B_g u = (n-2)u^q, & & \text{on } \partial M, \end{cases}$$

where

$$1 < 1 + \varepsilon_0 \leq q \leq \frac{n}{n-2}, \quad L_g = \Delta_g - \frac{n-2}{4(n-1)}R_g, \quad B_g = \frac{\partial}{\partial \nu_g} + \frac{n-2}{2}h_g.$$

Instead of looking for conformal metrics with zero scalar curvature and constant mean curvature as in (P) , one may also look for scalar flat conformal metrics with boundary mean curvature being a given function H ; this problem is equivalent to finding a smooth positive solution u to

$$\begin{cases} L_g u = 0, & u > 0, & \text{in } \overset{\circ}{M}, \\ B_g u = H u^{\frac{n}{n-2}}, & & \text{on } \partial M. \end{cases} \quad (P_H)$$

Such a problem was studied in [16] by Escobar, who proved that on a positive three dimensional smooth compact Riemannian manifold which is not conformally equivalent to the standard three dimensional ball, a necessary and sufficient condition for a C^2 function H to be the mean curvature of some conformal flat metric is that H is positive somewhere. We recall that a manifold is called of positive type if the quadratic part of the Euler functional associated to (P) is positive definite.

In our work we assume that the boundary is umbilic, that is the traceless part of the second fundamental form vanishes on the boundary. Moreover we assume that the function H is positive.

Our first theorem gives a priori estimates of solutions of $(P_{H,q})$ in $H^1(M)$ norm.

Theorem 1.1 *Let (M, g) be a three dimensional smooth compact Riemannian manifold with umbilic boundary. Then for all $\varepsilon_0 > 0$*

$$\|u\|_{H^1(M)} \leq C \quad \forall u \in \bigcup_{1+\varepsilon_0 \leq q \leq 3} \mathcal{M}_{H,q},$$

where C depends only on $M, g, \varepsilon_0, \|H\|_{C^2(\partial M)}$, and the positive lower bound of H .

Our next theorem states that for any positive C^2 function H , all such metrics stay bounded with respect to the C^2 norm and the total Leray-Schauder degree of all the solutions of (P_H) is -1 . In fact we establish a slightly stronger compactness result. Consider for $1 < q \leq 3$ the problem

$$\begin{cases} L_g u = 0, & u > 0, & \text{in } \mathring{M}, \\ B_g u = H u^q, & & \text{on } \partial M. \end{cases} \quad (P_{H,q})$$

We use $\mathcal{M}_{H,q}$ to denote the set of solutions of $P_{H,q}$ in $C^2(M)$. We have the following theorem.

Theorem 1.2 *Let (M, g) be a positive three dimensional smooth compact Riemannian manifold with umbilic boundary which is not conformally equivalent to the standard three dimensional ball. Then, for any $1 < q \leq 3$ and positive function $H \in C^2(\partial M)$, there exists some constant C depending only on $M, g, \|H\|_{C^2}$, the positive lower bound of H and $q - 1$ such that*

$$\frac{1}{C} \leq u \leq C \quad \text{and} \quad \|u\|_{C^2(M)} \leq C$$

for all solutions u of $(P_{H,q})$. Moreover the total degree of all solutions of $(P_{H,q})$ is -1 . Consequently, equation $(P_{H,3})$ has at least one solution.

We remark that the hypothesis that (M, g) is not conformally equivalent to the standard three dimensional ball is necessary since (P_H) may have no solution in this case due to the Kazdan-Warner's conditions for solvability. On the ball sufficient conditions on H in dimensions 3 and 4 are given in [13] and [17], and perturbative results were obtained in [9].

Finally, let us point out that recently S. Brendle [7, 8] obtained on surfaces some results related to ours. He used curvature flows methods, in the spirit of M. Struwe [32] and X. X. Chen [10]. The curvature flow method was introduced by R. Hamilton [20], and used by B. Chow [11], R. Ye [33], and Bartz-Struwe-Ye [6].

The remainder of the paper is organized as follows. In section 2 we provide the main local blow-up analysis giving first sharp pointwise estimates to a sequence of solutions near isolated simple blow-up points, then we prove that an isolated blow-up is in fact an isolated simple blow up, ruling out the possibility of bubbles on top of bubbles. In section 3 we rule out the possibility of bubble accumulations and establish Theorem 1.1. In section 4 we study compactness of solutions of (P_H) and establish Theorem 1.2. In the Appendix, we provide some standard descriptions of singular behaviour of positive solutions to some linear boundary value elliptic equations in punctured half balls and collect some useful results.

2 Local blow-up analysis

We may assume without loss of generality that $h_g \equiv 0$. Indeed, let φ_1 be a positive eigenfunction associated to the first eigenvalue λ_1 of the problem

$$\begin{cases} L_g \varphi = \lambda_1 \varphi, & \text{in } \overset{\circ}{M}, \\ B_g \varphi = 0, & \text{on } \partial M. \end{cases}$$

Setting $\tilde{g} = \varphi_1^4 g$ and $\tilde{u} = \varphi_1^{-1} u$, where u is a solution of $(P_{H,3})$, one can easily check that $R_{\tilde{g}} > 0$, $h_{\tilde{g}} \equiv 0$, and $\tilde{u}$ satisfies

$$\begin{cases} L_{\tilde{g}} \tilde{u} = 0, & \text{in } \overset{\circ}{M}, \\ \frac{\partial \tilde{u}}{\partial \nu} = H \tilde{u}^3, & \text{on } \partial M. \end{cases}$$

For sake of simplicity, we work with $\tilde{g}$, denoting it by g . Since ∂M is umbilic with respect to g , and $h_{\tilde{g}} = 0$, it follows that the second fundamental form vanishes at each point of the boundary, that is the boundary is a totally geodesic submanifold. Hence we can take conformal normal coordinates around any point of the boundary [15]

Let us first recall the definitions of isolated and isolated simple blow up which were first introduced by R. Schoen [30] and used extensively by Y. Y. Li [23, 24].

Definition 2.1 *Let (M, g) be a smooth compact n -dimensional Riemannian manifold with boundary and let $\bar{r} > 0$, $\bar{c} > 0$, $\bar{x} \in \partial M$, $H \in C^0(\overline{B_{\bar{r}}(\bar{x})})$ be some positive function where $B_{\bar{r}}(\bar{x})$ denotes the geodesic ball in (M, g) of radius $\bar{r}$ centered at $\bar{x}$. Suppose that, for some sequences $q_i = 3 - \tau_i$, $\tau_i \rightarrow 0$, $H_i \rightarrow H$ in $C^2(\overline{B_{\bar{r}}(\bar{x})})$, $\{u_i\}_{i \in \mathbb{N}}$ solves*

$$\begin{cases} L_g u_i = 0, & u_i > 0, & \text{in } B_{\bar{r}}(\bar{x}), \\ \frac{\partial u_i}{\partial \nu} = H_i u_i^{q_i}, & & \text{on } \partial M \cap B_{\bar{r}}(\bar{x}). \end{cases} \quad (2.1)$$

We say that $\bar{x}$ is an isolated blow-up point of $\{u_i\}_i$ if there exists a sequence of local maximum points x_i of u_i such that $x_i \rightarrow \bar{x}$ and, for some $C_1 > 0$,

$$\lim_{i \rightarrow \infty} u_i(x_i) = +\infty \quad \text{and} \quad u_i(x) \leq C_1 d(x, x_i)^{-\frac{1}{q_i-1}}, \quad \forall x \in B_{\bar{r}}(x_i), \quad \forall i.$$

To describe the behaviour of blowing-up solutions near an isolated blow-up point, we define spherical averages of u_i centered at x_i as follows

$$\bar{u}_i(r) = \oint_{M \cap \partial B_r(\bar{x})} u_i = \frac{1}{\text{Vol}_g(M \cap \partial B_r(\bar{x}))} \int_{M \cap \partial B_r(\bar{x})} u_i.$$

Now we define the notion of isolated simple blow-up point.

Definition 2.2 *Let $x_i \rightarrow \bar{x}$ be an isolated blow-up point of $\{u_i\}_i$ as in Definition 2.1. We say that $x_i \rightarrow \bar{x}$ is an isolated simple blow-up point of $\{u_i\}_i$ if, for some positive constants $\tilde{r} \in (0, \bar{r})$ and $C_2 > 1$, the function $\bar{w}_i(r) := r^{\frac{1}{q_i-1}} \bar{u}_i(r)$ satisfies, for large i ,*

$$\bar{w}'_i(r) < 0 \quad \text{for } r \text{ satisfying } C_2 u_i^{1-q_i}(x_i) \leq r \leq \tilde{r}.$$

For any $\bar{x} \in \partial M$, by choosing geodesic normal coordinate system centered at $\bar{x}$, we can assume without loss of generality that

$$\begin{aligned} \bar{x} = 0, \quad g_{ij}(0) = \delta_{ij}, \quad B_1^+(0) &:= \{x = (x^1, x^2, x^3) : |x| < 1 \text{ and } x^3 > 0\} \subset M, \\ \{(x', 0) = (x^1, x^2, 0) : |x'| < 1\} &\subset \partial M, \quad \Gamma_{ij}^k(0) = 0, \end{aligned}$$

where Γ_{ij}^k is the Christoffel symbol. For later use, we denote

$$\begin{aligned} \mathbb{R}_+^3 &= \{(x', x^3) \in \mathbb{R}^2 \times \mathbb{R} : x^3 > 0\}, \quad B_r^+(\bar{x}) = \{x = (x', x^3) \in \mathbb{R}_+^3 : |x - \bar{x}| < r\}, \\ B_r^+ &= B_r^+(0), \quad \Gamma_1(B_r^+(\bar{x})) = \partial B_r^+(\bar{x}) \cap \partial \mathbb{R}_+^3, \quad \Gamma_2(B_r(\bar{x})) = \partial B_r(\bar{x}) \cap \mathbb{R}_+^3. \end{aligned}$$

Let $H_i \rightarrow H$ in $C^2(\Gamma_1(B_3^+))$ be a sequence of positive functions, q_i be a sequence of numbers satisfying $2 \leq q_i \leq 3$ and $q_i \rightarrow 3$, and $\{v_i\}_i \subset C^2(\overline{B_3^+})$ be a sequence of solutions to

$$\begin{cases} -\Delta_g v_i + \frac{1}{8} R_g v_i = 0, & v_i > 0, \quad \text{in } B_3^+, \\ \frac{\partial v_i}{\partial \nu} = H_i v_i^{q_i}, & \text{on } \Gamma_1(B_3^+). \end{cases} \quad (P_i)$$

In this section, we start giving some properties of isolated and isolated simple blow-up. Hence forward we use c to denote positive constants which may vary from formula to formula and which may depend only on M , g , and $\bar{r}$. Such blow-up analysis was also carried out in [17], where (M, g) was the standard ball endowed with euclidean metric, see also our previous work [18].

The following lemma gives a Harnack Inequality, which proof is contained in [18, 17], Lemma 2.3, up to some minor modifications.

Lemma 2.3 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y} \in \Gamma_1(B_3^+)$ be an isolated blow-up of $\{v_i\}_i$. Then for any $0 < r < \bar{r}$, we have*

$$\max_{B_{2r}^+(y_i) \setminus B_{r/2}^+(y_i)} v_i \leq C_3 \min_{B_{2r}^+(y_i) \setminus B_{r/2}^+(y_i)} v_i,$$

where C_3 is some positive constant independent of i and r .

Lemma 2.4 *Let v_i satisfy (P_i) , $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated blow-up point. Then for any $R_i \rightarrow +\infty$, $\varepsilon_i \rightarrow 0^+$ we have that, after passing to a subsequence,*

$$\begin{aligned} & \left\| v_i^{-1}(y_i) v_i(\exp_{y_i}(v_i^{1-q_i}(y_i)x)) - \left[\frac{1}{(1+h_i x^3)^2 + h_i^2 |x'|^2} \right]^{1/2} \right\|_{C^1(B_{2R_i}^+)} \\ & + \left\| v_i^{-1}(y_i) v_i(\exp_{y_i}(v_i^{1-q_i}(y_i)x)) - \left[\frac{1}{(1+h_i x^3)^2 + h_i^2 |x'|^2} \right]^{1/2} \right\|_{H^1(B_{2R_i}^+)} \leq \varepsilon_i \end{aligned} \quad (2.2)$$

and

$$\frac{R_i}{\log v_i(y_i)} \xrightarrow{i \rightarrow +\infty} 0, \quad (2.3)$$

where $x = (x', x^3) \in B_1^+$ and $h_i = H_i(y_i)$.

Proof. Let $g_i = (g_i)_{\alpha\beta}(x) dx^\alpha dx^\beta = g_{\alpha\beta}(v_i^{1-q_i}(y_i)x) dx^\alpha dx^\beta$ denote the scaled metric. Set

$$\xi_i(x) = v_i^{-1}(y_i) v_i(y_i + v_i^{1-q_i}(y_i)x), \quad \text{for } x \in B_{v_i^{q_i-1}(y_i)}^{-T_i},$$

defined on the set

$$B_{v_i^{q_i-1}(y_i)}^{-T_i} := \{z \in \mathbb{R}^3 : |z| < v_i^{q_i-1}(y_i) \text{ and } z^3 > -T_i\}$$

where $T_i = y_i^3 v_i^{q_i-1}(y_i)$. Then $\xi_i(x)$ satisfies

$$\begin{cases} -\Delta_{g_i} \xi_i + \frac{1}{8} v_i^{2(1-q_i)}(y_i) R_{g_i}(y_i + v_i^{1-q_i}(y_i)x) \xi_i = 0, & \xi_i > 0, & \text{in } B_{v_i^{q_i-1}(y_i)}^{-T_i}, \\ \frac{\partial \xi_i}{\partial \nu_{g_i}} = H_i(y_i + v_i^{1-q_i}(y_i)x) \xi_i^{q_i} & \text{on } \partial B_{v_i^{q_i-1}(y_i)}^{-T_i} \cap \{z \in \mathbb{R}^3 : z^3 = -T_i\}, \\ \xi_i(0) = 1, \\ 0 \text{ is a local maximum point of } \xi_i, \\ 0 < \xi_i(x) \leq \tilde{c} |x|^{-\frac{1}{q_i-1}}, \end{cases} \quad (2.4)$$

for some positive constant $\tilde{c}$. Now we prove that ξ_i is locally bounded. Using Hopf Point Boundary Lemma and Lemma 2.3, we derive that for $0 < r < 1$

$$1 = \xi_i(0) \geq \min_{\Gamma_1(B_r^+)} \xi_i \geq \min_{\Gamma_2(B_r^+)} \xi_i \geq c \max_{\Gamma_2(B_r^+)} \xi_i$$

which implies that, for some c independent of r ,

$$\max_{\Gamma_2(B_r^+)} \xi_i \leq c.$$

Therefore, we derive easily that ξ_i is locally bounded. Applying standard elliptic estimates to $\{\xi_i\}$, we have, after passing to a subsequence, that $\xi_i \rightarrow \xi$ in $C_{\text{loc}}^2(\mathbb{R}_+^3)$ and $H_{\text{loc}}^1(\mathbb{R}_+^3)$ for some ξ satisfying

$$\begin{cases} \Delta \xi = 0, & \xi > 0, & \text{in } \mathbb{R}_{-T}^3, \\ \frac{\partial \xi}{\partial \nu} = \left[\lim_i H_i(y_i) \right] \xi^3, & \text{on } \partial \mathbb{R}_{-T}^3, \end{cases}$$

where $\mathbb{R}_{-T}^3 := \{x = (x', x^3) \in \mathbb{R}^3 : x^3 > -T\}$ and $T = \lim_i T_i$. By the Liouville Theorem and the last estimate of (2.4) we have that $T < +\infty$. By Li-Zhu [26] Liouville type Theorem (see Theorem A.3 of the Appendix), we easily deduce that $T = 0$ and

$$\xi(x', x^3) = \left[\frac{1}{(1 + \lim_i H_i(y_i) x^3)^2 + (\lim_i H_i(y_i))^2 |x'|^2} \right]^{1/2}.$$

Lemma 2.4 is proved. $\square$

Before stating our next result, we point out that it follows from Lemma A.5 of the Appendix that, for $\delta_0 > 0$ small enough, there exists a unique function $G(\cdot, \bar{y}) \in C^2(\overline{B_{\delta_0}^+(\bar{y})} \setminus \{\bar{y}\})$ satisfying

$$\begin{cases} -\Delta_g G(\cdot, \bar{y}) + \frac{1}{8} R_g G(\cdot, \bar{y}) = 0, & \text{in } B_{\delta_0}^+(\bar{y}), \\ \frac{\partial}{\partial \nu} G(\cdot, \bar{y}) = 0, & \text{on } \Gamma_1(B_{\delta_0}^+(\bar{y})) \setminus \{\bar{y}\}, \\ \lim_{y \rightarrow \bar{y}} d(y, \bar{y}) G(y, \bar{y}) = 1. \end{cases}$$

Now we state our main estimate on isolated simple blow-up points.

Proposition 2.5 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up point, with (2.2) and (2.3) for all i . Then for some positive constant C depending only on $C_1, \tilde{r}, \|H_i\|_{C^2(\Gamma_1(B_1^+))}$, and $\inf_{y \in \Gamma_1(B_1^+)} H_i(y)$ we have*

$$v_i(y) \leq C v_i^{-1}(y_i) d(y, y_i)^{-1}, \quad \text{for } d(y, y_i) \leq \frac{\tilde{r}}{2} \quad (2.5)$$

where C_1 and $\tilde{r}$ are given in Definitions 2.1 and 2.2. Furthermore, after passing to some subsequence, for some positive constant b ,

$$v_i(y_i) v_i \xrightarrow{i \rightarrow +\infty} b G(\cdot, \bar{y}) + E \quad \text{in } C_{\text{loc}}^2(\overline{B_{\tilde{\rho}}^+(\bar{y})} \setminus \{\bar{y}\})$$

where $\tilde{\rho} = \min(\delta_0, \tilde{r}/2)$ and $E \in C^2(B_{\tilde{\rho}}^+(\bar{y}))$ satisfies

$$\begin{cases} -\Delta_g E + \frac{1}{8} R_g E = 0, & \text{in } B_{\tilde{\rho}}^+, \\ \frac{\partial E}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{\tilde{\rho}}^+). \end{cases}$$

Proposition 2.5 will be established through a series of lemmas.

Lemma 2.6 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up. Assume $R_i \rightarrow +\infty$ and $0 < \varepsilon_i < e^{-R_i}$ are sequences for which (2.2) and (2.3) hold. Then for any given $0 < \delta < 1/100$, there exists $\rho_1 \in (0, \tilde{r})$ which is independent of i (but depending on δ), such that*

$$v_i(y_i) \leq C_4 v_i^{-\lambda_i}(y_i) d(y, y_i)^{-1+\delta}, \quad \forall r_i \leq d(y, y_i) \leq \rho_1, \quad (2.6)$$

$$\nabla_g v_i(y_i) \leq C_4 v_i^{-\lambda_i}(y_i) d(y, y_i)^{-2+\delta}, \quad \forall r_i \leq d(y, y_i) \leq \rho_1, \quad (2.7)$$

$$\nabla_g^2 v_i(y_i) \leq C_4 v_i^{-\lambda_i}(y_i) d(y, y_i)^{-3+\delta}, \quad \forall r_i \leq d(y, y_i) \leq \rho_1, \quad (2.8)$$

where $r_i = R_i v_i^{1-q_i}(y_i)$, $\lambda_i = (1-\delta)(q_i-1)-1$, and C_4 is some positive constant independent of i .

Proof. We assume, for simplicity, that g is the flat metric. The general case can be derived essentially in the same way. Let $r_i = R_i v_i^{1-q_i}(y_i)$, it follows from Lemma 2.4 that

$$v_i(y) \leq c v_i(y_i) R_i^{-1}, \quad \text{for } d(y, y_i) = r_i. \quad (2.9)$$

We then derive from Lemma 2.3, (2.9), and the definition of isolated simple blow-up that, for $r_i \leq d(y, y_i) \leq \tilde{r}$, we have

$$v_i^{q_i-1}(y) \leq c R_i^{-1+o(1)} d(y, y_i)^{-1}. \quad (2.10)$$

Set $T_i = y_i^3 v_i^{q_i-1}(y_i)$. From the proof of Lemma 2.4 we know that $\lim_i T_i = 0$. It is not restrictive to take $y_i = (0, 0, y_i^3)$. Thus we have $d(0, y_i^3) = o(r_i)$. So

$$B_1^+(0) \setminus B_{2r_i}^+(0) \subset \left\{ \frac{3}{2} r_i \leq d(y, y_i) \leq \frac{3}{2} \right\}.$$

Let us apply the Maximum Principle stated in Theorem A.1 in the Appendix; to this aim set

$$\varphi_i(y) = M_i (|y|^{-\delta} - \varepsilon |y|^{\delta-1} y^3) + A v_i^{-\lambda_i}(y_i) (|y|^{-1+\delta} - \varepsilon |y|^{-2+\delta} y^3)$$

with M_i and A to be chosen later, and let Φ_i be the boundary operator defined by

$$\Phi_i(v) = \frac{\partial v}{\partial \nu} - H_i v_i^{q_i-1}(y_i) v.$$

A direct computation yields

$$\Delta \varphi_i(y) = M_i |y|^{-\delta} [-\delta(1-\delta) + O(\varepsilon)] + |y|^{-(3-\delta)} A v_i^{-\lambda_i}(y_i) [-\delta(1-\delta) + O(\varepsilon)].$$

So one can choose $\varepsilon = O(\delta)$ such that $\Delta \varphi_i \leq 0$.

Another straightforward computation taking into account (2.10) shows that for $\delta > 0$ there exists $\rho_1(\delta) > 0$ such that

$$\Phi_i \varphi_i > 0 \quad \text{on } \Gamma_1(B_{\rho_1}^+).$$

Taking

$$\begin{aligned} \Omega &= D_i = B_{\rho_1}^+ \setminus B_{2r_i}^+(0) \\ \Sigma &= \Gamma_1(D_i), & \Gamma &= \Gamma_2(D_i), \\ V &\equiv 0, & h &= H_i v_i^{q_i-1}, \\ \psi &= v_i, & v &= \varphi_i - v_i, \end{aligned}$$

and choosing $A = O(\delta)$ such that $\varphi_i \geq 0$ on $\Gamma_2(D_i)$ and $M_i = \max_{\Gamma_1(B_{\rho_1}^+)} v_i$, we deduce from Theorem A.1 of the Appendix that

$$v_i(x) \leq \varphi_i(x). \quad (2.11)$$

By the Harnack inequality and the assumption that the blow-up is isolated simple, we derive that

$$M_i \leq c v_i^{-\lambda_i}(y_i). \quad (2.12)$$

The estimate (2.6) of the lemma follows from (2.11) and (2.12).

To derive (2.7) from (2.6), we argue as follows. For $r_i \leq |\tilde{y}| \leq \rho_1/2$, we consider

$$w_i(z) = |\tilde{y}|^{1-\delta} v_i^{\lambda_i}(y_i) v_i(|\tilde{y}|z), \quad \text{for } \frac{1}{2} \leq |z| \leq 2, \quad z^3 \geq 0.$$

It follows from (P_i) that w_i satisfies

$$\begin{cases} -\Delta w_i = 0, & \text{in } \{\frac{1}{2} < |z| < 2 : z^3 > 0\}, \\ \frac{\partial w_i}{\partial \nu} = H_i(|\tilde{y}|z) |\tilde{y}|^{-\lambda_i} v_i^{\lambda_i(1-q_i)}(y_i) w_i^{q_i}, & \text{on } \{\frac{1}{2} < |z| < 2 : z^3 = 0\}. \end{cases} \quad (2.13)$$

In view of (2.6), we have $w_i(z) \leq c$ for any $\frac{1}{2} \leq |z| \leq 2, z^3 \geq 0$. We then derive from (2.13) and gradient elliptic estimates that

$$|\nabla w_i(z)| \leq c, \quad z \in \Gamma_2(B_1^+)$$

which implies that

$$|\nabla v_i(\tilde{y})| \leq c |\tilde{y}|^{-2+\delta} v_i^{-\lambda_i}(y_i).$$

This establishes (2.7). Estimate (2.8) can be derived in a similar way. We omit the details. Lemma 2.6 is thus established. $\square$

Later on we will fix δ close to 0, hence fix ρ_1 . Our aim is to obtain (2.6) with $\delta = 0$ for $r_i \leq d(y, y_i) \leq \rho_1$, which together with Lemma 2.4 yields Proposition 2.5.

Now we state the following Pohozaev type identity, which is basically contained in Li-Zhu [27]. In the following, we write in some geodesic normal coordinate $x = (x^1, x^2, x^3)$ with $g_{ij}(0) = \delta_{ij}$ and $\Gamma_{ij}^k(0) = 0$. We use also the notation $\nabla = (\partial_1, \partial_2, \partial_3)$, $dx = dx^1 \wedge dx^2 \wedge dx^3$ and ds to denote the surface area element with respect to the flat metric.

Lemma 2.7 *For $H \in C^2(\Gamma_1(B_1^+))$ and $a \in C^2(\Gamma_1(B_1^+))$, let $u \in C^2(\overline{B_1^+})$ satisfy, for $q > 0$,*

$$\begin{cases} -\Delta_g u + \frac{1}{8} R_g u = 0, & u > 0, \quad \text{in } B_1^+, \\ \frac{\partial u}{\partial \nu} = H u^q, & \text{on } \Gamma_1(B_1^+); \end{cases}$$

then we have, for any r such that $0 < r \leq 1$,

$$\begin{aligned} & \frac{1}{q+1} \int_{\Gamma_1(B_r^+)} (x' \cdot \nabla_{x'} H) u^{q+1} ds + \left(\frac{2}{q+1} - \frac{1}{2} \right) \int_{\Gamma_1(B_r^+)} H u^{q+1} ds \\ & - \frac{1}{16} \int_{B_r^+} (x \cdot \nabla R_g) u^2 dx - \frac{1}{8} \int_{B_r^+} R_g u^2 dx - \frac{r}{16} \int_{\Gamma_2(B_r^+)} R_g u^2 ds \\ & - \frac{r}{q+1} \int_{\partial \Gamma_1(B_r^+)} H u^{q+1} ds = \int_{\Gamma_2(B_r^+)} B(r, x, u, \nabla u) ds + A(g, u) \end{aligned}$$

where

$$B(r, x, u, \nabla u) = \frac{1}{2} \frac{\partial u}{\partial \nu} u + \frac{1}{2} r \left(\frac{\partial u}{\partial \nu} \right)^2 - \frac{1}{2} r |\nabla_T u|^2, \quad (2.14)$$

$\nabla_T u$ denotes the component of ∇u which is tangent to $\Gamma_2(B_r^+)$,

$$\begin{aligned} A(g, u) &= \int_{B_r^+} (x^k \partial_k u) (g_{ij} - \delta_{ij}) \partial_{ij} u dx - \int_{B_r^+} (x^l \partial_l u) (g_{ij} - \Gamma_{ij}^k \partial_k u) dx \\ &+ \frac{1}{2} \int_{B_r^+} u (g^{ij} - \delta^{ij}) \partial_{ij} u dx - \frac{1}{2} \int_{B_r^+} u g^{ij} \Gamma_{ij}^k \partial_k u dx \\ &- \int_{\Gamma_1(B_r^+)} x^i \frac{\partial u}{\partial x_i} (g^{ij} - \delta^{ij}) \frac{\partial u}{\partial x_i} \nu_j - \frac{n-2}{2} \int_{\Gamma_1(B_r^+)} (g^{ij} - \delta^{ij}) \frac{\partial u}{\partial x_i} \nu_j u, \end{aligned} \quad (2.15)$$

and Γ_{ij}^k denotes the Christoffel symbol.

Regarding the term $A(g, u_i)$, where u_i is a solution of (P_i) , we have the following estimate, the proof of which is a direct consequence of Lemma 2.4 and Lemma 2.6.

Lemma 2.8 *Let $\{v_i\}_i$ satisfy (P_i) , $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up point. Assume $R_i \rightarrow +\infty$ and $0 < \varepsilon_i < e^{-R_i}$ are sequences for which (2.2) and (2.3) hold. Then, for $0 < r < \rho_1$, we have*

$$|A(g, v_i)| \leq C_5 r v_i^{-2\lambda_i}(y_i)$$

where C_5 is some constant independent of i and r .

Using Lemma 2.4, Lemma 2.6, Lemma 2.7, Lemma 2.8, and standard elliptic estimates, we derive the following estimate about the rate of blow-up of the solutions of (P_i) .

Lemma 2.9 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up point. Assume $R_i \rightarrow +\infty$ and $0 < \varepsilon_i < e^{-R_i}$ are sequences for which (2.2) and (2.3) hold. Then*

$$\tau_i = O(v_i^{-2\lambda_i}(y_i)).$$

Consequently $v_i^{\tau_i}(y_i) \rightarrow 1$ as $i \rightarrow \infty$.

Lemma 2.10 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up point. Then, for $0 < r < \tilde{r}/2$, we have*

$$\limsup_{i \rightarrow +\infty} \max_{y \in \Gamma_2(B_r^+(y_i))} v_i(y_i) v_i(y) \leq C(r).$$

Proof. Due to Lemma 2.3, it is enough to establish the lemma for $r > 0$ sufficiently small. Without loss of generality we may take $\tilde{r} = 1$. Pick any $y_r \in \Gamma_2(B_r^+)$ and set

$$\xi_i(y) = v_i^{-1}(y_r) v_i(y),$$

then ξ_i satisfies

$$\begin{cases} -\Delta_g \xi_i + \frac{1}{8} R_g \xi_i = 0, & \text{in } B_{1/2}^+(\bar{y}), \\ \frac{\partial \xi_i}{\partial \nu} = H_i v_i^{q_i-1}(y_r) \xi_i^{q_i}, & \text{on } \Gamma_1(B_{1/2}^+(\bar{y})). \end{cases}$$

It follows from Lemma 2.3 that for any compact set $K \subset B_{1/2}^+(\bar{y}) \setminus \{\bar{y}\}$, there exists some constant $c(K)$ such that

$$c(K)^{-1} \leq \xi_i \leq c(K), \quad \text{on } K.$$

We also know from (2.6) that $v_i(y_r) \rightarrow 0$ as $i \rightarrow +\infty$. Then by elliptic theories, we have, after passing to a subsequence, that $\xi_i \rightarrow \xi$ in $C_{\text{loc}}^2(B_{1/2}^+(\bar{y}) \setminus \{\bar{y}\})$, where ξ satisfies

$$\begin{cases} -\Delta_g \xi + \frac{1}{8} R_g \xi = 0, & \text{in } B_{1/2}^+(\bar{y}), \\ \frac{\partial \xi}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{1/2}^+(\bar{y}) \setminus \{\bar{y}\}). \end{cases}$$

From the assumption that $y_i \rightarrow \bar{y}$ is an isolated simple blow-up point of $\{v_i\}_i$, we know that the function $r^{1/2}\bar{\xi}(r)$ is nonincreasing in the interval $(0, \tilde{r})$ and so we deduce that ξ is singular at $\bar{y}$. So it follows from Corollary A.8 in the Appendix that for r small enough there exists some positive constant $m > 0$ independent of i such that for i large we have

$$-\frac{1}{8} \int_{B_r^+} R_g \xi_i = \int_{B_r^+} -\Delta_g \xi_i = - \int_{\Gamma_1(B_r^+)} \frac{\partial \xi_i}{\partial \nu} - \int_{\Gamma_2(B_r^+)} \frac{\partial \xi_i}{\partial \nu} > m - \int_{\Gamma_1(B_r^+)} \frac{\partial \xi_i}{\partial \nu}$$

which implies that

$$-\frac{1}{8} \int_{B_r^+} R_g \xi_i + \int_{\Gamma_1(B_r^+)} \frac{\partial \xi_i}{\partial \nu} > m. \quad (2.16)$$

On the other hand

$$\int_{\Gamma_1(B_r^+)} \frac{\partial \xi_i}{\partial \nu} = \int_{\Gamma_1(B_r^+)} H_i v_i^{q_i-1}(y_r) \xi_i^{q_i} \leq v_i^{-1}(y_r) \int_{\Gamma_1(B_r^+)} H_i v_i^{q_i}. \quad (2.17)$$

Using Lemma 2.4 and Lemma 2.6, we derive that

$$\int_{\Gamma_1(B_r^+)} H_i v_i^{q_i} \leq c v_i^{-1}(y_i). \quad (2.18)$$

Hence our lemma follows from (2.16), (2.17), and (2.18). $\square$

Now we are able to give the proof of Proposition 2.5.

Proof of Proposition 2.5. We first establish (2.5) arguing by contradiction. Suppose the contrary; then, possibly passing to a subsequence still denoted as v_i , there exists a sequence $\{\tilde{y}_i\}_i$ such that $d(\tilde{y}_i, y_i) \leq \tilde{r}/2$ and

$$v_i(\tilde{y}_i) v_i(y_i) d(\tilde{y}_i, y_i) \xrightarrow{i \rightarrow +\infty} +\infty. \quad (2.19)$$

Set $\tilde{r}_i = d(\tilde{y}_i, y_i)$. From Lemma 2.4 it is clear that $\tilde{r}_i \geq r_i = R_i v_i^{1-q_i}(y_i)$. Set

$$\tilde{v}_i(x) = \tilde{r}_i^{\frac{1}{q_i-1}} v_i(y_i + \tilde{r}_i x) \quad \text{in } B_2^{-T_i}, \quad T_i = \tilde{r}_i^{-1} y_i^3.$$

Clearly $\tilde{v}_i$ satisfies

$$\begin{cases} -\Delta_{g_i} \tilde{v}_i + \frac{1}{8} \tilde{R}_{g_i} \tilde{v}_i = 0, & v_i > 0, \quad \text{in } B_2^{-T_i}, \\ \frac{\partial \tilde{v}_i}{\partial \nu} = \tilde{H}_i(x) \tilde{v}_i^{q_i}(x), & \text{on } \partial B_2^{-T_i} \cap \{x^3 - T_i\}, \end{cases}$$

where

$$\begin{aligned} (g_i)_{\alpha\beta} &= g_{\alpha\beta}(\tilde{r}_i x) dx^\alpha dx^\beta, \\ \tilde{R}_{g_i}(x) &= \tilde{r}_i^2 R_{g_i}(y_i + \tilde{r}_i x), \end{aligned}$$

and

$$\tilde{H}_i(x) = H_i(y_i + \tilde{r}_i x).$$

Lemma 2.10 yields that

$$\max_{x \in \Gamma_2(B_{1/2}^+)} \tilde{v}_i(0) \tilde{v}_i(x) \leq c$$

for some positive constant c , and so

$$v_i(\tilde{y}_i) v_i(y_i) d(y_i, y_i) \leq c.$$

This contradicts (2.19). Therefore (2.5) is established. Take now

$$w_i(x) = v_i(y_i) v_i(x).$$

From (P_i) it is clear that w_i satisfies

$$\begin{cases} -\Delta_g w_i + \frac{1}{8} R_g w_i = 0, & \text{in } B_3^+, \\ \frac{\partial w_i}{\partial \nu} = H_i(x) v_i^{1-q_i}(y_i) w_i^{q_i}, & \text{on } \Gamma_1(B_3^+). \end{cases}$$

Estimate (2.5) implies that $w_i(x) \leq c d(x, y_i)^{-1}$. Since $y_i \rightarrow \bar{y}$, w_i is locally bounded in any compact set not containing $\bar{y}$. Then, up to a subsequence, $w_i \rightarrow w$ in $C_{\text{loc}}^2(B_{\bar{\rho}}(\bar{y}) \setminus \{\bar{y}\})$ for some $w > 0$ satisfying

$$\begin{cases} -\Delta_g w + \frac{1}{8} R_g w = 0, & \text{in } B_{\bar{\rho}}^+(\bar{y}), \\ \frac{\partial w}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{\bar{\rho}}^+) \setminus \{\bar{y}\}. \end{cases}$$

From Proposition A.7 of the Appendix, we have that

$$w = b G(\cdot, \bar{y}) + E, \quad \text{in } B_{\bar{\rho}}^+ \setminus \{0\},$$

where $b \geq 0$, E is a regular function satisfying

$$\begin{cases} -\Delta_g E + \frac{1}{8} R_g E = 0, & \text{in } B_{\bar{\rho}}^+, \\ \frac{\partial E}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{\bar{\rho}}^+), \end{cases}$$

and $G \in C^2(B_{\bar{\rho}}^+ \setminus \{\bar{y}\})$ satisfies

$$\begin{cases} -L_g G(\cdot, \bar{y}) = 0, & \text{in } B_{\bar{\rho}}^+, \\ \frac{\partial G_a}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{\bar{\rho}}^+) \setminus \{\bar{y}\}, \end{cases}$$

and $\lim_{y \rightarrow \bar{y}} d(y, \bar{y})G(y, \bar{y})$ is a constant. Moreover w is singular at $\bar{y}$. Indeed from the definition of isolated simple blow-up we know that the function $r^{1/2}\bar{w}(r)$ is nonincreasing in the interval $(0, \tilde{r})$, which implies that w is singular at the origin and hence $b > 0$. The proof of Proposition 2.5 is thereby complete. $\square$

Using Proposition 2.5, one can strengthen the results of Lemmas 2.6 and 2.8 just using (2.5) instead of (2.6), thus obtaining the following corollary.

Corollary 2.11 *Let $\{v_i\}_i$ satisfy (P_i) , $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up point. Assume $R_i \rightarrow +\infty$ and $0 < \varepsilon_i < e^{-R_i}$ are sequences for which (2.2) and (2.3) hold. Then there exists $\rho_1 \in (0, \tilde{r})$ such that*

$$|\nabla_g v_i(y)| \leq C_4 v_i^{-1}(y_i) d(y, y_i)^{-2}, \quad \text{for all } r_i \leq d(y, y_i) \leq \rho_1, \quad (2.20)$$

and

$$|\nabla_g^2 v_i(y)| \leq C_4 v_i^{-1}(y_i) d(y, y_i)^{-3}, \quad \text{for all } r_i \leq d(y, y_i) \leq \rho_1, \quad (2.21)$$

where $r_i = R_i v_i^{1-q_i}(y_i)$ and C_4 is some positive constant independent of i . Moreover

$$|A(g, v_i)| \leq C_5 r v_i^{-2}(y_i),$$

for some positive constant C_5 independent of i .

Let us prove an upper bound estimate for $\nabla_g H_i(y_i)$.

Lemma 2.12 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y} \in \Gamma_1(B_1^+)$ be an isolated simple blow-up point. Then*

$$\nabla_g H_i(y_i) = O(v_i^{-2}(y_i)).$$

Proof. Let $x = (x^1, x^2, x^3)$ be some geodesic normal coordinates centered at y_i and η some smooth cut-off function such that

$$\eta(x) = \begin{cases} 1, & \text{if } x \in \overline{B_{1/4}^+}, \\ 0, & \text{if } x \notin \overline{B_{1/2}^+}, \end{cases}$$

and $0 \leq \eta \leq 1$. Multiply (P_i) by $\eta \frac{\partial v_i}{\partial x_1}$ and integrate by parts over B_1^+ , thus obtaining

$$0 = \int_{B_1^+} \nabla_g v_i \cdot \nabla \left(\eta \frac{\partial v_i}{\partial x_1} \right) dV + \frac{1}{8} \int_{B_1^+} R_g v_i \eta \frac{\partial v_i}{\partial x_1} - \int_{\Gamma_1(B_{1/2}^+)} \frac{\partial v_i}{\partial \nu} \eta \frac{\partial v_i}{\partial x_1} d\sigma. \quad (2.22)$$

From (P_i) , (2.5), and (2.2) we have that

$$\begin{aligned}
& \int_{\Gamma_1(B_{1/2}^+)} \frac{\partial v_i}{\partial \nu} \eta \frac{\partial v_i}{\partial x_1} d\sigma + \frac{1}{8} \int_{B_1^+} R_g v_i \eta \frac{\partial v_i}{\partial x_1} \\
&= \int_{\Gamma_1(B_{1/2}^+)} H_i v_i^{q_i} \eta \frac{\partial v_i}{\partial x_1} d\sigma + O(v_i^{-2}(y_i)) \\
&= -\frac{1}{q_i + 1} \frac{\partial H_i}{\partial x_1}(y_i) \int_{\Gamma_1(B_{1/2}^+)} \eta v_i^{q_i+1} d\sigma + O\left(\int_{\Gamma_1(B_{1/2}^+)} |x'| v_i^{q_i+1}\right) + O(v_i^{-2}(y_i)) \\
&= -\frac{1}{q_i + 1} \frac{\partial H_i}{\partial x_1}(y_i) \int_{\Gamma_1(B_{1/2}^+)} \eta v_i^{q_i+1} d\sigma + O(v_i^{-2}(y_i)). \tag{2.23}
\end{aligned}$$

On the other hand, from (2.20) it follows that

$$\begin{aligned}
& \int_{\Gamma_1(B_1^+)} \nabla_g v_i \cdot \nabla_g \left(\eta \frac{\partial v_i}{\partial x_1} \right) d\sigma \\
&= \int_{B_1^+} (\nabla_g v_i \cdot \nabla_g \eta) \frac{\partial v_i}{\partial x_1} dV + \int_{B_1^+} \nabla_g v_i \cdot \eta \nabla_g \left(\frac{\partial v_i}{\partial x_1} \right) dV \\
&= -\frac{1}{2} \int_{B_{1/2}^+ \setminus B_{1/4}^+} \frac{\partial \eta}{\partial x_1} |\nabla_g v_i|^2 dV + O(v_i^{-2}(y_i)) = O(v_i^{-2}(y_i)). \tag{2.24}
\end{aligned}$$

Putting all together (2.22), (2.23), and (2.24), we find

$$\frac{\partial H_i}{\partial x_1}(y_i) = O(v_i^{-2}(y_i)).$$

Repeating the same argument for the derivatives with respect to x_2 and x_3 , we come to the required estimate. $\square$

Corollary 2.13 *Under the same assumptions of Lemma 2.12, one has that*

$$\int_{\Gamma_1(B_r^+)} x' \cdot \nabla_{x'} H_i v_i^{q_i+1} d\sigma = O(v_i^{-4}(y_i)).$$

Proof. We have that

$$\begin{aligned}
\int_{\Gamma_1(B_r^+)} x' \cdot \nabla_{x'} H_i v_i^{q_i+1} d\sigma &= \int_{\Gamma_1(B_r^+)} \nabla_{x'} H_i(y_i) \cdot (x' - y_i) v_i^{q_i+1} d\sigma \\
&\quad + O\left(\int_{\Gamma_1(B_r^+)} |x'|^2 v_i^{q_i+1} d\sigma\right).
\end{aligned}$$

Since, using Proposition 2.5 and Lemma 2.4, $\int_{\Gamma_1(B_r^+)} (x' - y_i) v_i^{q_i+1} d\sigma = O(v_i^{-2}(y_i))$, from the previous lemma, Corollary 2.11, and (2.2), we reach the conclusion. $\square$

Proposition 2.14 *Let v_i satisfy (P_i) , $y_i \rightarrow \bar{y}$ be an isolated simple blow-up point with, for some $\tilde{\rho} > 0$,*

$$v_i(y_i)v_i \xrightarrow{i \rightarrow +\infty} h, \quad \text{in } C_{\text{loc}}^2(B_{\tilde{\rho}}^+(\bar{y}) \setminus \{\bar{y}\}).$$

Assume, for some $\beta > 0$, that in some geodesic normal coordinate system $x = (x^1, x^2, x^3)$

$$h(x) = \frac{\beta}{|x|} + A + o(1), \quad \text{as } |x| \rightarrow 0.$$

Then $A \leq 0$.

Proof. For $r > 0$ small, the Pohozaev type identity of Lemma 2.7 yields

$$\begin{aligned} & \frac{1}{q_i + 1} \int_{\Gamma_1(B_r^+)} (x' \cdot \nabla_{x'} H_i) v_i^{q_i+1} ds + \left(\frac{2}{q_i + 1} - \frac{1}{2} \right) \int_{\Gamma_1(B_r^+)} H_i v_i^{q_i+1} ds \\ & - \frac{1}{16} \int_{B_r^+} (x \cdot \nabla R_g) v_i^2 dx - \frac{1}{8} \int_{B_r^+} R_g v_i^2 dx - \frac{r}{16} \int_{\Gamma_2(B_r^+)} R_g v_i^2 ds \\ & - \frac{r}{q_i + 1} \int_{\partial \Gamma_1(B_r^+)} H_i v_i^{q_i+1} = \int_{\Gamma_2(B_r^+)} B(r, x, v_i, \nabla v_i) ds + A(g, v_i) \end{aligned} \quad (2.25)$$

where B and $A(g, v_i)$ are defined in (2.14) and (2.15) respectively. Multiply (2.25) by $v_i^2(y_i)$ and let $i \rightarrow \infty$. Using Corollary 2.11, Lemma 2.4, and Corollary 2.13, one has that

$$\lim_{r \rightarrow 0^+} \int_{\Gamma_2(B_r^+)} B(r, x, h, \nabla h) = \lim_{r \rightarrow 0^+} \limsup_{i \rightarrow \infty} v_i^2(y_i) \int_{\Gamma_2(B_r^+)} B(r, x, v_i, \nabla v_i) \geq 0. \quad (2.26)$$

On the other hand, a direct calculation yields

$$\lim_{r \rightarrow 0^+} \int_{\Gamma_2(B_r^+)} B(r, x, h, \nabla h) = -c A \quad (2.27)$$

for some $c > 0$. The conclusion follows from (2.26) and (2.27). $\square$

Now we can prove that an isolated blow-up point is in fact an isolated simple blow-up point.

Proposition 2.15 *Let v_i satisfy (P_i) and $y_i \rightarrow \bar{y}$ be an isolated blow-up point. Then $\bar{y}$ must be an isolated simple blow-up point.*

Proof. The proof is basically the same as that of Proposition 2.11 of [18]. For the reader's convenience, we include the proof here. From Lemma 2.4, it follows that

$$\bar{w}'_i(r) < 0 \quad \text{for every } C_2 v_i^{1-q_i}(y_i) \leq r \leq r_i. \quad (2.28)$$

Suppose that the blow-up is not simple; then there exist some sequences $\tilde{r}_i \rightarrow 0^+$, $\tilde{c}_i \rightarrow +\infty$ such that $\tilde{c}_i v_i^{1-q_i}(y_i) \leq \tilde{r}_i$ and, after passing to a subsequence,

$$\bar{w}'_i(\tilde{r}_i) \geq 0. \quad (2.29)$$

From (2.28) and (2.29) it is clear that $\tilde{r}_i \geq r_i$ and $\bar{w}_i$ has at least one critical point in the interval $[r_i, \tilde{r}_i]$. Let μ_i be the smallest critical point of $\bar{w}_i$ in this interval. We have that

$$\tilde{r}_i \geq \mu_i \geq r_i \quad \text{and} \quad \lim_{i \rightarrow \infty} \mu_i = 0.$$

Let $g_i = (g_i)_{\alpha\beta} dx^\alpha dx^\beta = g_{\alpha\beta}(\mu_i x) dx^\alpha dx^\beta$ be the scaled metric and

$$\xi_i(x) = \mu_i^{\frac{1}{q_i-1}} v_i(y_i + \mu_i x).$$

Then ξ_i satisfies

$$\left\{ \begin{array}{ll} -\Delta_{g_i} \xi_i + \frac{1}{8} R_{g_i} \xi_i = 0, & \text{in } B_{1/\mu_i}^{-T_i}, \\ \frac{\partial \xi_i}{\partial \nu} = \tilde{H}_i(x) \xi_i^{q_i}, & \text{on } \partial B_{1/\mu_i}^{-T_i} \cap \{x^3 = -T_i\}, \\ \lim_{i \rightarrow \infty} \xi_i(0) = \infty & \text{and } 0 \text{ is a local maximum point of } \xi_i, \\ r^{\frac{1}{q_i-1}} \bar{\xi}_i(r) & \text{has negative derivative in } c \xi_i(0)^{1-q_i} < r < 1, \\ \frac{d}{dr} \left(r^{\frac{1}{q_i-1}} \bar{\xi}_i(r) \right) \Big|_{r=1} = 0, & \end{array} \right. \quad (2.30)$$

where $T_i = \mu_i^{-1} y_i^3$, $\tilde{a}_i(x) = \mu_i a_i(y_i + \mu_i x)$, and $\tilde{H}_i(x) = H_i(y_i + \mu_i x)$. Arguing as in the proof of Lemma 2.4, we can easily prove that $T_i \rightarrow 0$. Since 0 is an isolated simple blow-up point, by Proposition 2.5 and Lemma 2.3, we have that, for some $\beta > 0$,

$$\xi_i(0) \xi_i \xrightarrow{i \rightarrow +\infty} h = \beta |x|^{-1} + E \quad \text{in } C_{\text{loc}}^2(\mathbb{R}_+^3 \setminus \{0\}) \quad (2.31)$$

with E satisfying

$$\left\{ \begin{array}{ll} -\Delta E = 0, & \text{in } \mathbb{R}_+^3, \\ \frac{\partial E}{\partial \nu} = 0, & \text{on } \partial \mathbb{R}_+^3. \end{array} \right.$$

By the Maximum Principle we have that $E \geq 0$. Reflecting E to be defined on all $\mathbb{R}^3$ and thus using the Liouville Theorem, we deduce that E is a constant. Using the last equality in (2.30) and (2.31), we deduce that $E \equiv b$. Therefore, $h(x) = b(G_a(x, \bar{y}) + 1)$ and this fact contradicts Proposition 2.14. $\square$

3 Ruling out bubble accumulations

Now we can proceed as in [18] to obtain the following results which rule out the possible accumulations of bubbles, and this implies that only isolated blow-up points may occur to blowing-up sequences of solutions.

Proposition 3.1 *Let (M, g) be a smooth compact three dimensional Riemannian manifold with umbilic boundary. For any $R \geq 1$, $0 < \varepsilon < 1$, there exist positive constants δ_0 , c_0 , and c_1 depending only on M , g , $\|H\|_{C^2(\partial M)}$, $\inf_{y \in \partial M} H(y)$, R , and ε , such that for all u in*

$$\bigcup_{3-\delta_0 \leq q \leq 3} \mathcal{M}_{H,q}$$

with $\max_M u \geq c_0$, there exists $\mathcal{S} = \{p_1, \dots, p_N\} \subset \partial M$ with $N \geq 1$ such that

- (i) each p_i is a local maximum point of u in M and

$$\overline{B_{\bar{r}_i}(p_i)} \cap \overline{B_{\bar{r}_j}(p_j)} = \emptyset, \quad \text{for } i \neq j,$$

where $\bar{r}_i = Ru^{1-q}(p_i)$ and $\overline{B_{\bar{r}_i}(p_i)}$ denotes the geodesic ball in (M, g) of radius $\bar{r}_i$ and centered at p_i ;

- (ii)

$$\left\| u^{-1}(p_i)u(\exp_{p_i}(yu^{1-q}(p_i))) - \left(\frac{1}{(1+hx^3)^2 + h^2|x'|^2} \right)^{1/2} \right\|_{C^2(B_{2R}^M(0))} < \varepsilon$$

where

$$B_{2R}^M(0) = \{y \in T_{p_i}M : |y| \leq 2R, u^{1-q}(p_i)y \in \exp_{p_i}^{-1}(B_\delta(p_i))\},$$

$y = (y', y^n) \in \mathbb{R}^n$, and $h > 0$;

- (iii) $d^{\frac{1}{q-1}}(p_j, p_i)u(p_j) \geq c_0$, for $j > i$, while $d(p, \mathcal{S})^{\frac{1}{q-1}}u(p) \leq c_1$, $\forall p \in M$, where $d(\cdot, \cdot)$ denotes the distance function in metric g .

Proposition 3.2 *Let (M, g) be a smooth compact three dimensional Riemannian manifold with umbilic boundary. For suitably large R and small $\varepsilon > 0$, there exist δ_1 and d depending only on M , g , $\|a\|_{C^2(\partial M)}$, $\|H\|_{C^2(\partial M)}$, $\inf_{y \in \partial M} H(y)$, R , and ε , such that for all u in*

$$\bigcup_{3-\delta_1 \leq q \leq 3} \mathcal{M}_{a,H,q}$$

with $\max_M u \geq c_0$, we have

$$\min\{d(p_i, p_j) : i \neq j, 1 \leq i, j \leq N\} \geq d$$

where $c_0, p_1, \dots, p_N$ are given by Proposition 3.1.

The previous two propositions imply that any blow-up point is in fact an isolated blow-up point. Thanks to Proposition 2.15, any blow-up point is in fact an isolated simple blow-up point.

Proof of Theorem 1.1. Arguing by contradiction, suppose that there exist some sequences $q_i \rightarrow q \in]1, 3]$, $u_i \in \mathcal{M}_{H, q_i}$ such that $\|u_i\|_{H^1(M)} \rightarrow +\infty$ as $i \rightarrow \infty$, which, in view of standard elliptic estimates, implies that $\max_M u_i \rightarrow +\infty$.

From Hu [22] (see also [25]), we know that $q = 3$. By Proposition 3.2, we have that for some small $\varepsilon > 0$, large $R > 0$, and some $N \geq 1$ there exist $y_i^{(1)}, \dots, y_i^{(N)} \in \partial M$ such that (i-iii) of Proposition 3.1 hold. $\{y_i^{(1)}\}_i, \dots, \{y_i^{(N)}\}_i$ are isolated blow-up points and hence, by Proposition 2.15, isolated simple blow-up points. From (2.2) and Proposition 2.5, we have that $\{\|u_i\|_{H^1(M)}\}_i$ is bounded, thus finding a contradiction. Theorem 1.1 is thereby established. $\square$

4 Compactness of the solutions

Before proving Theorem 1.2, we state the following result about the compactness of solutions of $(P_{H, q})$ when q stays strictly below the critical exponent. The proof is basically the same as the proof of Theorem 3.1 of [18].

Theorem 4.1 *Let (M, g) be a smooth compact three dimensional Riemannian manifold with umbilic boundary. Then for any $\delta_1 > 0$ there exists a constant $C > 0$ depending only on $M, g, \delta_1, \|H\|_{C^2(\partial M)}$, and the positive lower bound of H on ∂M such that for all $u \in \bigcup_{1+\delta_1 \leq q \leq 3-\delta_1} \mathcal{M}_{H, q}$ we have*

$$\frac{1}{C} \leq u(x) \leq C, \quad \forall x \in M; \quad \|u\|_{C^2(M)} \leq C.$$

Now we prove Theorem 1.2.

Proof of Theorem 1.2. Due to elliptic estimates and Lemma 2.3, we have to prove just the L^∞ bound, i.e. $u \leq C$. Suppose the contrary; then there exist a sequence $q_i \rightarrow q \in]1, 3]$ with

$$u_i \in \mathcal{M}_{H, q_i}, \quad \text{and} \quad \max_M u_i \rightarrow +\infty,$$

where $\bar{c}$ is some positive constant independent of i . From Theorem 4.1, we have that q must be 3. It follows from Proposition 2.15 and Proposition 3.2 that, after passing to a

subsequence, $\{u_i\}_i$ has N ($1 \leq N < \infty$) isolated simple blow-up points denoted by $y^{(1)}, \dots, y^{(N)}$. Let $y_i^{(\ell)}$ denotes the local maximum points as in Definition 2.1. It follows from Proposition 2.5 that

$$u_i(y_i^{(1)})u_i \xrightarrow{i \rightarrow +\infty} h(y) = \sum_{j=1}^N b_j G(y, y^{(j)}) + E(y) \quad \text{in } C_{\text{loc}}^2(M \setminus \{y^{(1)}, \dots, y^{(N)}\}),$$

where $b_j > 0$ and $E \in C^2(M)$ satisfies

$$\begin{cases} -L_g E = 0, & \text{in } M, \\ \frac{\partial E}{\partial \nu} = 0, & \text{on } \partial M. \end{cases} \quad (4.1)$$

Since the manifold is of positive type we have that $E \equiv 0$. Therefore,

$$u_i(y_i^{(1)})u_i \xrightarrow{i \rightarrow +\infty} h(y) = \sum_{j=1}^N b_j G_a(y, y^{(j)}) \quad \text{in } C_{\text{loc}}^2(M \setminus \{y^{(1)}, \dots, y^{(N)}\}).$$

Let $x = (x^1, x^2, x^3)$ be some geodesic normal coordinate system centered at $y_i^{(1)}$. From Lemma A.5 of the Appendix, the Positive Mass Theorem, and the assumption that the manifold is not conformally equivalent to the standard ball, we derive that there exists a positive constant A such that

$$h(x) = h(\exp_{y_i^{(1)}}(x)) = c|x|^{-1} + A_i + O(|x|^{-\alpha}) \quad \text{for } |x| \text{ close to } 0$$

and $A_i \geq A > 0$. This contradicts the result of Proposition 2.14. The compactness part of Theorem 1.2 is proved.

Since we have compactness, we can proceed as in section 4 of [18] to prove that the total degree of the solutions is -1 . Theorem 1.2 is established. $\square$

Appendix

In this Appendix, we recall some well known results and provide some description of singular behaviour of positive solutions to some boundary value elliptic equations in punctured half balls.

For $n \geq 3$ let B_r^+ denote the set $\{x = (x', x^n) \in \mathbb{R}^n = \mathbb{R}^{n-1} \times \mathbb{R} : |x| < r \text{ and } x^n > 0\}$ and set $\Gamma_1(B_r^+) := \partial B_r^+ \cap \partial \mathbb{R}_+^n$, $\Gamma_2(B_r^+) := \partial B_r^+ \cap \mathbb{R}_+^n$. Throughout this section, let $g = g_{ij} dx^i dx^j$ denote some smooth Riemannian metric in B_1^+ and $a \in C^1(\Gamma_1(B_1^+))$.

First of all we recall the following Maximum Principle; for the proof see [21].

Theorem A.1 *Let Ω be a bounded domain in $\mathbb{R}^n$ and let $\partial\Omega = \Gamma \cup \Sigma$, $V \in L^\infty(\Omega)$, and $h \in L^\infty(\Sigma)$ such that there exists some $\psi \in C^2(\Omega) \cap C^1(\overline{\Omega})$, $\psi > 0$ in $\overline{\Omega}$ satisfying*

$$\begin{cases} \Delta_g \psi + V\psi \leq 0, & \text{in } \Omega, \\ \frac{\partial \psi}{\partial \nu} \geq h\psi, & \text{on } \Sigma. \end{cases}$$

If $v \in C^2(\Omega) \cap C^1(\overline{\Omega})$ satisfies

$$\begin{cases} \Delta_g v + Vv \leq 0, & \text{in } \Omega, \\ \frac{\partial v}{\partial \nu} \geq hv, & \text{on } \Sigma, \\ v \geq 0, & \text{on } \Gamma, \end{cases}$$

then $v \geq 0$ in $\overline{\Omega}$.

We state now the following Maximum Principle which holds for the operator T defined by

$$Tu = v \quad \text{if and only if} \quad \begin{cases} L_g u = 0, & \text{in } \mathring{M}, \\ \frac{\partial u}{\partial \nu} = v, & \text{on } \partial M. \end{cases}$$

Proposition A.2 [16] *Let (M, g) be a Riemannian manifold with boundary of positive type. Then for any $u \in C^2(M) \cap C^1(M)$ satisfying*

$$\begin{cases} L_g u \geq 0, & \text{in } \mathring{M}, \\ \frac{\partial u}{\partial \nu} \leq 0, & \text{on } \partial M, \end{cases}$$

we have $u \leq 0$ in M .

Proof. Let $u^+(x) = \max\{0, u(x)\}$. Then

$$0 \leq \int_M (L_g u) u^+ dV - \int_{\partial M} \frac{\partial u}{\partial \nu} u^+ d\sigma = - \int_M |\nabla_g u^+|^2 dV - \frac{1}{8} \int_M R_g^2 |u^+|^2 dV.$$

Sine M is of positive type $\int |\nabla_g u|^2 + \frac{1}{8} \int R_g u^2$ is an equivalent norm hence $u^+ \equiv 0$. $\square$

We now recall the following Louville type Theorem by Li and Zhu [26].

Theorem A.3 *If v is a solution of*

$$\begin{cases} -\Delta v = 0, & \text{in } \mathbb{R}_+^n, \\ \frac{\partial v}{\partial x^n} = cv^{\frac{n}{n-2}}, & \text{on } \partial \mathbb{R}_+^n, \end{cases}$$

and c is a negative constant, then either $v \equiv 0$ or v is of the form

$$v(x', x^n) = \left[\frac{\varepsilon}{(x_0^n + x^n)^2 + |x' - x'_0|^2} \right]^{\frac{n-2}{2}}, \quad x' \in \mathbb{R}^{n-1}, \quad x^n \in \mathbb{R},$$

where $x_0^n = -\frac{(n-2)\varepsilon}{c}$, for some $\varepsilon > 0$, and $x'_0 \in \mathbb{R}^{n-1}$.

Lemma A.4 Suppose that $u \in C^2(B_1^+ \setminus \{0\})$ is a solution of

$$\begin{cases} -L_g u = 0, & \text{on } B_1^+, \\ \frac{\partial u}{\partial \nu} = 0, & \text{on } \Gamma_1(B_1^+ \setminus \{0\}), \end{cases} \quad (\text{A.1})$$

and $u(x) = o(|x|^{2-n})$ as $|x| \rightarrow 0$. Then $u \in C^{2,\alpha}(B_{1/2}^+)$ for any $0 < \alpha < 1$.

Proof. We make a reflection cross $\Gamma_1(B_1^+)$ to extend u as a solution of $-L_g u = 0$ on B_1^+ , then we use [19] to conclude that 0 is a removable singularity, then the result follows from standard elliptic regularity. $\square$

Lemma A.5 There exists some constant $\delta_0 > 0$ depending only on n , $\|g_{ij}\|_{C^2(B_1^+)}$ and $\|H\|_{L^\infty(B_1^+)}$ such that for all $0 < \delta < \delta_0$ there exists some function G satisfying

$$\begin{cases} -L_g G = 0, & \text{in } B_\delta^+, \\ \frac{\partial G}{\partial \nu} = 0, & \text{on } \Gamma_1(B_\delta^+) \setminus \{0\}, \\ \lim_{|x| \rightarrow 0} |x|^{-1} G(x) = 1 \end{cases} \quad (\text{A.2})$$

such that, for some A constant and some $\alpha \in (0, 1)$, $\forall x \in B_\delta^+$

$$G(x) = |x|^{-1} + A + O(|x|^\alpha).$$

Proof. Reflecting across $\Gamma_1(B_\delta^+)$, the lemma is reduced to Proposition B.1 in [27] $\square$

Making again reflection across $\Gamma_1(B_1^+)$, we derive from Lemma 9.3 in [27], the following

Lemma A.6 Assume that $u \in C^2(B_1^+ \setminus \{0\})$ satisfies

$$\begin{cases} -L_g u = 0, & \text{in } B_1^+, \\ \frac{\partial u}{\partial \nu} = 0, & \text{on } \Gamma_1(B_1^+) \setminus \{0\}, \end{cases}$$

then

$$\alpha = \limsup_{r \rightarrow 0^+} \max_{x \in \Gamma_2(B_r^+)} u(x) |x|^{n-2} < +\infty.$$

Proposition A.7 *Suppose that $u \in C^2(B_1^+ \setminus \{0\})$ satisfies*

$$\begin{cases} -L_g u = 0, & \text{in } B_1^+, \\ \frac{\partial u}{\partial \nu} = 0, & \text{on } \Gamma_1(B_1^+) \setminus \{0\}. \end{cases} \quad (\text{A.3})$$

Then there exists some constant $b \geq 0$ such that

$$u(x) = bG(x) + E(x) \quad \text{in } B_{1/2}^+ \setminus \{0\},$$

where G is defined in Lemma A.5, and $E \in C^2(B_1^+)$ satisfies

$$\begin{cases} -L_g E = 0, & \text{in } B_{1/2}^+, \\ \frac{\partial E}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{1/2}^+). \end{cases} \quad (\text{A.4})$$

Proof. Set

$$b = b(u) = \sup \{ \lambda \geq 0 : \lambda G \leq u \text{ in } \overline{B_{\delta_0}^+} \setminus \{0\} \}. \quad (\text{A.5})$$

By the previous lemma we know that

$$0 \leq b \leq \alpha < +\infty.$$

Two cases may occur.

Case 1: $b = 0$.

In this case we claim that

$$\forall \varepsilon > 0 \quad \exists r_\varepsilon \in (0, \delta_0) : \min_{x \in \Gamma_2(B_{r_\varepsilon}^+)} \{u(x) - \varepsilon G(x)\} \leq 0, \text{ for any } 0 < r < r_\varepsilon.$$

To prove the claim argue by contradiction. Suppose that the claim is false. Then there exist $\varepsilon_0 > 0$ and a sequence $r_j \rightarrow 0^+$ such that

$$\min_{|x|=r_j} \{u(x) - \varepsilon_0 G(x)\} > 0 \quad \text{and} \quad u(x) - \varepsilon_0 G(x) > 0 \text{ on } \Gamma_2(B_{\delta_0}^+).$$

Let us prove that $\varepsilon_0 \leq b$, which gives a contradiction. To do this, we want to prove that

$$u - \varepsilon_0 G \geq 0 \quad \text{in } B_{\delta_0}^+ \setminus \{0\}.$$

Note that $u - \varepsilon_0 G$ satisfies

$$\begin{cases} -\Delta_g(u - \varepsilon_0 G) + \frac{1}{8} R_g(u - \varepsilon_0 G) = 0, & \text{in } B_{\delta_0}^+, \\ \frac{\partial}{\partial \nu}(u - \varepsilon_0 G) = 0, & \text{on } \Gamma_1(B_{\delta_0}^+) \setminus \{0\}. \end{cases}$$

Apply Theorem A.1 with

$$v = u - \varepsilon_0 G, \quad \Sigma = \Gamma_1(B_{\delta_0}^+) \setminus \Gamma_1(B_{r_j}^+), \quad \Gamma = \Gamma_2(B_{r_j}^+) \cup \Gamma_2(B_{\delta_0}^+),$$

thus getting $u - \varepsilon_0 G \geq 0$ in the annulus $B_{\delta_0}^+ \setminus B_{r_j}^+$ for any j , and consequently in $B_{\delta_0}^+ \setminus \{0\}$. Therefore $\varepsilon_0 \leq b$ and so there is a contradiction. This proves the claim. Hence, for any $\varepsilon > 0$ and $0 < r < r_\varepsilon$ there exists $x_\varepsilon \in \Gamma_2(B_r^+)$ such that

$$u(x_\varepsilon) \leq \varepsilon G(x_\varepsilon).$$

By the Harnack inequality of Lemma 2.3 we have that

$$\max_{|x|=r} u(x) \leq c u(x_\varepsilon) \leq c \varepsilon G(x_\varepsilon).$$

Since $G(x) \sim |x|^{2-n}$ for $|x|$ small, we conclude that

$$u(x) = o(|x|^{2-n}) \quad \text{for } |x| \sim 0.$$

Therefore from Lemma A.4 we obtain that u is regular. Setting $E(x) = u(x)$, the conclusion in this case follows.

Case 2: $b > 0$.

We consider $v(x) = u(x) - b G(x)$ in $\overline{B_{\delta_0}^+} \setminus \{0\}$. By definition of b , it is clear that $v \geq 0$ in $\overline{B_{\delta_0}^+} \setminus \{0\}$. Moreover v satisfies

$$\begin{cases} -\Delta_g v + \frac{1}{8} R_g v = 0, & \text{in } B_{\delta_0}^+, \\ \frac{\partial v}{\partial \nu} = 0, & \text{on } \Gamma_1(B_{\delta_0}^+) \setminus \{0\}, \end{cases}$$

so that from the Maximum Principle we know that either $v \equiv 0$ or $v > 0$ in $B_{\delta_0}^+ \setminus \{0\}$. If $v \equiv 0$, take $E \equiv 0$ and we are done. Otherwise $v > 0$ and satisfies the same equation as u . Set

$$\tilde{b} = b(v) = \sup \{ \lambda \geq 0 : \lambda G \leq v \text{ in } \overline{B_{\delta_0}^+} \setminus \{0\} \}.$$

If $\lambda \geq 0$ and $\lambda G \leq v$ in $B_{\delta_0}^+ \setminus \{0\}$, then $\lambda G \leq u - b G$ with $b > 0$, i.e. $(\lambda + b)G \leq u$. By definition of b , this implies that $\lambda + b \leq b$, i.e. $\lambda \leq 0$ and so $\lambda = 0$. Therefore $\tilde{b} = 0$. Arguing as in Case 1, we can prove that $v(x) = o(|x|^{2-n})$ for $|x| \sim 0$. Lemma A.4 ensures that v is regular, so that choosing $E(x) = v(x)$ we are done.

The proof of Proposition A.7 is thereby complete. $\square$

Finally we prove the following corollary.

Corollary A.8 *Let u be a solution of (A.3) which is singular at 0. Then*

$$\lim_{r \rightarrow 0^+} \int_{\Gamma_2(B_r^+)} \frac{\partial u}{\partial \nu} d\sigma = b \cdot \lim_{r \rightarrow 0^+} \int_{\Gamma_2(B_r^+)} \frac{\partial G}{\partial \nu} d\sigma = -\frac{n-2}{2} b |\mathbb{S}^{n-1}|,$$

where $\mathbb{S}^{n-1}$ denotes the standard n -dimensional sphere and $b > 0$ is given by Proposition A.7.

Proof. From the previous proposition, we know that

$$u(x) = b G(x) + E(x), \quad \text{in } B_{1/2}^+(0) \setminus \{0\}, \quad b \geq 0.$$

Since u is singular at 0, b must be strictly positive. From (A.4), we have

$$0 = - \int_{B_r^+} \Delta_g E dV - \int_{\Gamma_2(B_r^+)} \frac{\partial E}{\partial \nu} d\sigma + \frac{1}{8} \int_{B_r^+} R_g E.$$

Hence, since E is regular, we obtain

$$\int_{\Gamma_2(B_r^+)} \frac{\partial E}{\partial \nu} d\sigma = \frac{1}{8} \int_{B_r^+} R_g(x) E(x) d\sigma \xrightarrow{r \rightarrow 0^+} 0$$

and so

$$\lim_{r \rightarrow 0^+} \int_{\Gamma_2(B_r^+)} \frac{\partial u}{\partial \nu} d\sigma = \lim_{r \rightarrow 0^+} b \int_{\Gamma_2(B_r^+)} \frac{\partial G}{\partial \nu} d\sigma.$$

From Lemma A.5 we know that G is of the form

$$G(x) = |x|^{-1} + \mathcal{R}(x)$$

where $\mathcal{R}$ is regular. Since

$$\int_{\Gamma_2(B_r^+)} \frac{\partial}{\partial \nu} |x|^{-1} d\sigma = -\frac{1}{2} |\mathbb{S}^{n-1}|$$

and

$$\int_{\Gamma_2(B_r^+)} \frac{\partial \mathcal{R}}{\partial \nu} d\sigma \xrightarrow{r \rightarrow 0^+} 0,$$

we conclude that

$$\lim_{r \rightarrow 0^+} \int_{\Gamma_2(B_r^+)} \frac{\partial u}{\partial \nu} d\sigma = -\frac{1}{2} b |\mathbb{S}^{n-1}|$$

thus getting the conclusion. $\square$
